# 12. Dynamic Data Structures & Generics

Harald Gall, Prof. Dr.

Institut für Informatik Universität Zürich

http://seal.ifi.uzh.ch

# **Objectives**

- Define and use an instance of ArrayList
- Describe general idea of linked list data structures and implementation
- Manipulate linked lists
- Use inner classes in defining linked data structures
- Describe, create, use iterators
- Define, us classes with generic types

### Array-Based Data Structures: Outline

The Class ArrayList
Creating an Instance of ArrayList
Using Methods of ArrayList
Programming Example: A To-Do List
Parameterized Classes and Generic
Data Types

- Consider limitations of Java arrays
  - Array length is not dynamically changeable
  - Possible to create a new, larger array and copy elements – but this is awkward, contrived
- More elegant solution is use instance of ArrayList
  - Length is changeable at run time

- Drawbacks of using ArrayList
  - Less efficient than using an array
  - Can only store objects
  - Cannot store primitive types
- Implementation
  - Actually does use arrays
  - Expands capacity in manner previously suggested

- Class ArrayList is an implementation of an Abstract Data Type (ADT) called a *list*
- Elements can be added
  - At end
  - At beginning
  - In between items
- Possible to edit, delete, access, and count entries in the list

#### Methods of class ArrayList

#### public ArrayList<Base\_Type>(int initialCapacity)

Creates an empty list with the specified *Base\_Type* and initial capacity. The *Base\_Type* must be a class type; it cannot be a primitive type such as int or double. When the list needs to increase its capacity, the capacity doubles.

#### public ArrayList<Base\_Type>()

Behaves like the previous constructor, but the initial capacity is ten.

#### public boolean add(Base\_Type newElement)

Adds the specified element to the end of this list and increases the list's size by 1. The capacity of the list is increased if that is required. Returns true if the addition is successful.

#### public void add(int index, Base\_Type newElement)

Inserts the specified element at the specified index position of this list. Shifts elements at subsequent positions to make room for the new entry by increasing their indices by 1. Increases the list's size by 1. The capacity of the list is increased if that is required. Throws IndexOutOfBoundsException if index < 0 or index > size().

#### Methods of class ArrayList

#### public Base\_Type get(int index)

Returns the element at the position specified by index. Throws IndexOutOfBounds-Exception if index < 0 or index  $\ge size()$ .

#### public Base\_Type set(int index, Base\_Type element)

Replaces the element at the position specified by index with the given element. Returns the element that was replaced. Throws IndexOutOfBoundsException if index < 0 or index  $\ge size()$ .

#### public Base\_Type remove(int index)

Removes and returns the element at the specified index. Shifts elements at subsequent positions toward position index by decreasing their indices by 1. Decreases the list's size by 1. Throws IndexOutOfBoundsException if index < 0 or index ≥ size().

#### public boolean remove(Object element)

Removes the first occurrence of element in this list, and shifts elements at subsequent positions toward the removed element by decreasing their indices by 1. Decreases the list's size by 1. Returns true if element was removed; otherwise returns false and does not alter the list.

# Creating Instance of ArrayList

Necessary to import java.util.ArrayList;

Create and name instance

```
ArrayList<String> list =
  new ArrayList<String>(20);
```

- This list will
  - Hold String objects
  - Initially hold up to 20 elements

# Using Methods of ArrayList

- Object of an ArrayList used like an array
  - But methods must be used
  - Not square bracket notation
- Given

```
ArrayList<String> aList =
   new ArrayList<String> (20);
```

Assign a value with

```
aList.add(index, "Hi Mom");
aList.set(index, "Yo Dad");
```

# Programming Example

- A To-Do List
  - Maintains a list of everyday tasks
  - User enters as many as desired
  - Program displays the list
- View <u>source code</u>
  class ArrayListDemo

# Programming Example

```
Enter items for the list, when prompted.
Type an entry:
Buy milk
More items for the list? yes
Type an entry:
Wash car
More items for the list? yes
Type an entry:
                                                       Sample
Do assignment
                                                       screen
More items for the list? no
The list contains:
                                                       output
Buy milk
Wash car
Do assignment
```

# Programming Example

- When accessing all elements of an ArrayList object
  - Use a For-Each loop
- Use the trimToSize method to save memory
- To copy an ArrayList
  - Do not use just an assignment statement
  - Use the clone method, e.g. aList.clone()

### Parameterized Classes, Generic Data Types

- Class ArrayList is a parameterized class
  - It has a parameter which is a type
- Possible to declare our own classes which use types as parameters
- Note earlier versions of Java had a type of ArrayList that was <u>not</u> parameterized

### Linked Data Structures:Outline

The Class LinkedList

Node Inner Classes

**Iterators** 

The Java Iterator Interface

**Exception Handling with Linked Lists** 

Variations on a Linked List

Other Linked Data Structures

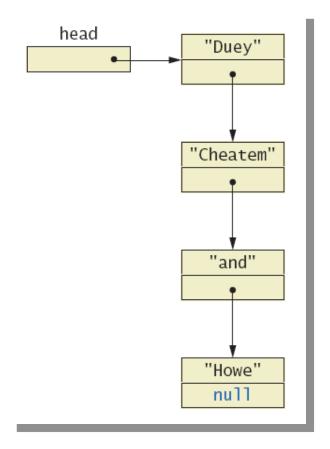

#### Class LinkedList

- Linked data structure
  - Collection of objects
  - Each object contains data and a reference to another object in the collection
- Java provides a class to do this, LinkedList
  - More efficient memory use than ArrayList
- We will write our own version to learn the concepts of a linked list

### **Linked Lists**

- A dynamic data structure
- Links items in a list to one another

### **Linked Lists**

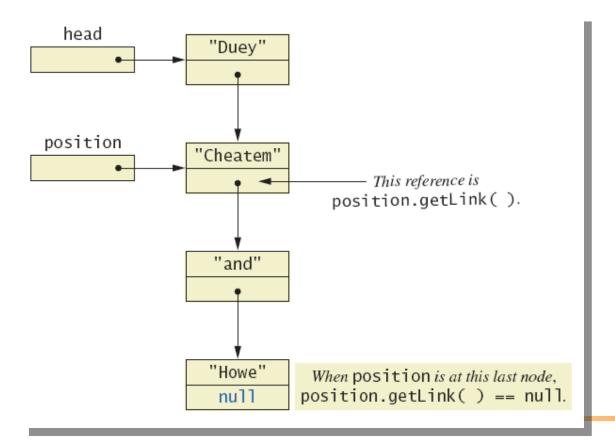

- Node of a linked list object requires two instance variables
  - Data
  - Link
- View <u>sample class</u>

#### class ListNode

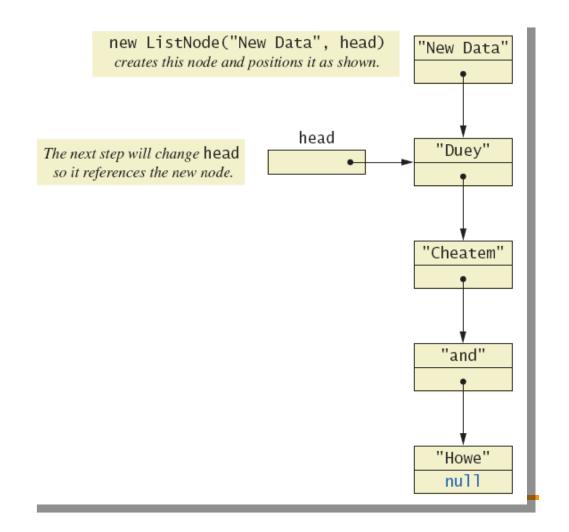

- This example has String data
- Note the link, a reference to the type which is the class

- Now we create a linked list class which uses the node class
- View <u>class</u>
  class <u>StringLinkedList</u>
- Note the single instance variable of type
   ListNode
- Note method to traverse and print the contents of the list

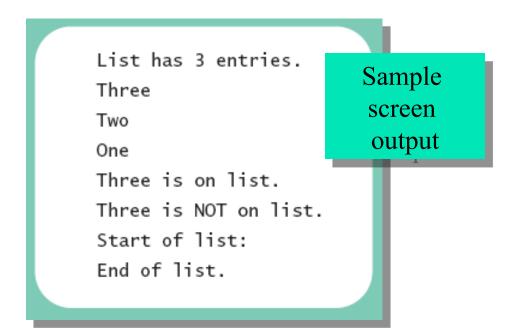

Moving down a linked list

 Adding a node at the start of a linked list

View linked-list <u>demonstration</u>
 class StringLinkedListDemo

- Java automatically returns memory used by deleted node to the operating system.
  - Called automatic garbage collection
- In this context, note the significance of NullPointerException messages
- Consider the fact that our program has a reference (name) to only the head node

# A Privacy Leak

- Note results of getLink in class ListNode
  - Returns reference to ListNode
  - This is a reference to an instance variable of a class type ... which is supposed to be private
- Typical solution is to make ListNode a private inner class of StringLinkedList

### Inner Classes

- Defined within other classes
- Example

```
public class OuterClass
{
    Declarations_of_OuterClass_Instance_Variables
    Definitions_of_OuterClass_Methods

private class InnerClass
{
    Declarations_of_InnerClass_Instance_Variables
    Definitions_of_InnerClass_Methods
}
}
```

### Inner Classes

- Inner class definition local to the outer-class definition
  - Inner-class definition usable anywhere within definition of outer class
- Methods of inner and outer classes have access to each other's methods, instance variables

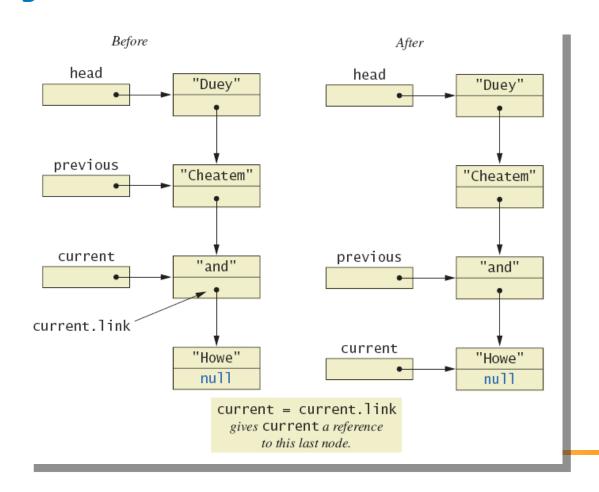

#### Node Inner Classes

- We show ListNode as a private inner class
  - This is safer design
  - Hides method getLink from world outside
     StringLinkedList definition
- View <u>new version</u>, listing 12.5
   class <u>StringLinkedListSelfContained</u>

- A variable that allows you to step through a collection of nodes in a linked list
  - For arrays, we use an integer
- Common to place elements of a linked list into an array
  - For display purposes, array is easily traversed
- View <u>method</u> to do this, listing 12.6 method toArray

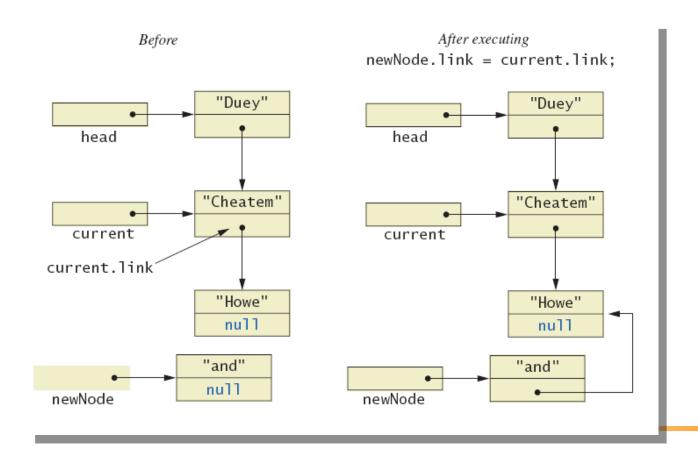

- Consider an iterator that will move through a linked list
  - Allow manipulation of the data at the nodes
  - Allow insertion, deletion of nodes
- View sample code
   class StringLinkedListWithIterator

The effect of goToNext on a linked list

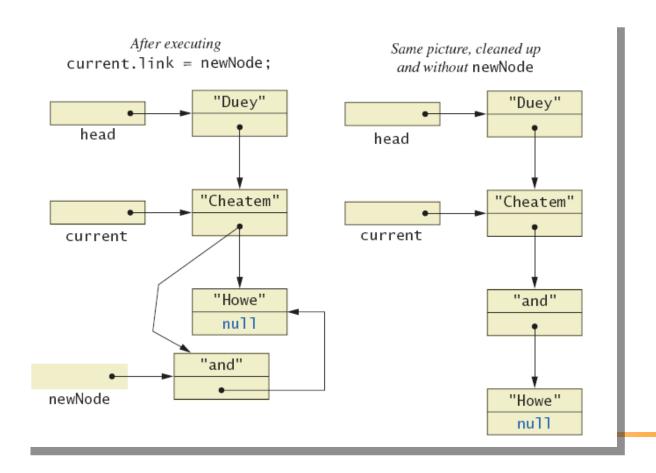

Adding node to linked list using

#### insertAfterIterator

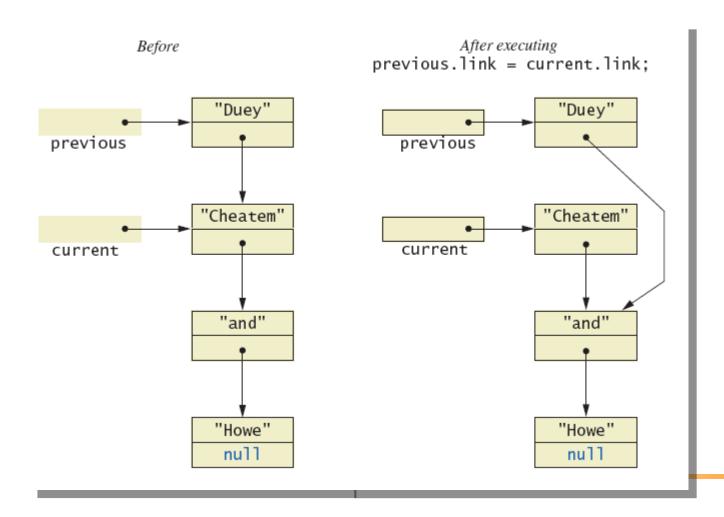

Adding node to linked list using

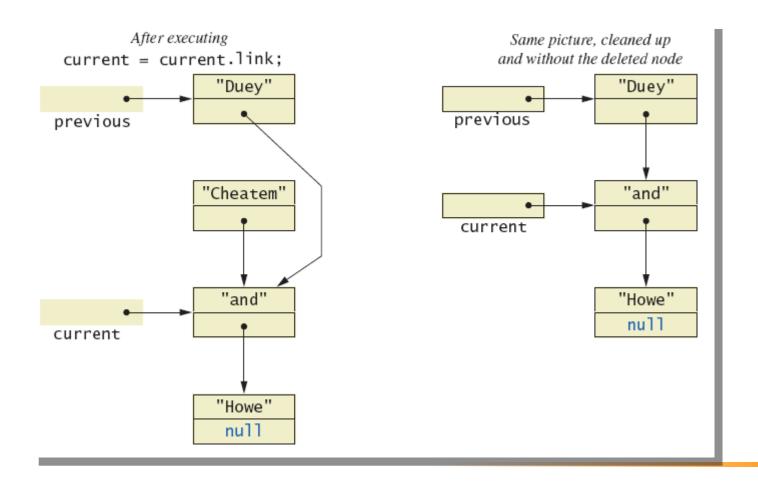

#### insertAfterIterator

#### Deleting a node

### Deleting a node

#### Java Iterator Interface

- Java formally considers an iterator to be an object
- Note interface named Iterator with methods
  - hasNext returns boolean value
  - next returns next element in iteration
  - remove removes element most recently returned by next method

### **Exception Handling with Linked Lists**

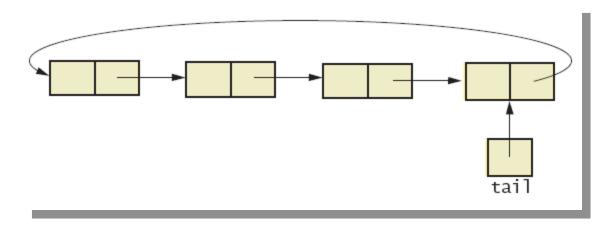

- Recall class StringLinkedListWithIterator
  - Methods written so that errors caused screen message and program end
- More elegant solution is to have them throw exceptions
  - Programmer decides how to handle
- Note class which does this class LinkedListException

#### Variations on a Linked List

- Possible to make a linked list where data element is of any type
  - Replace type String in definition of node class with desired data type
- Consider keeping a reference to last node in list
  - Called the tail of the list
  - Constructors, methods modified to accommodate new reference

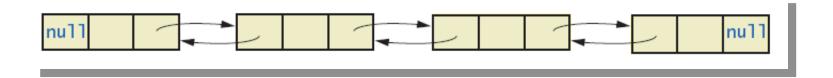

#### Variations on a Linked List

- Consider having last link point back to head
  - Creates a circular linked list
- Circular linked list

#### Variations on a Linked List

- Also possible to have backward as well as forward links in the list
  - Doubly linked list
  - Possible to traverse in either direction
- Doubly linked list

### Other Linked Data Structures

#### Stack

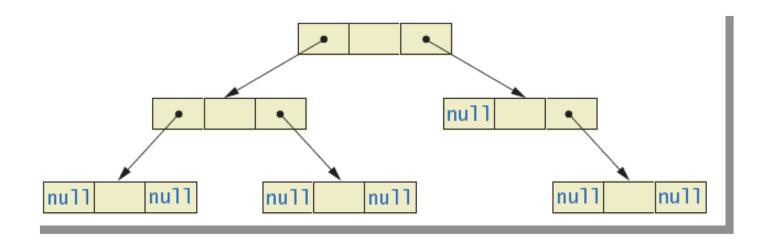

- Elements removed from ADT in reverse order of initial insertion
- Can be implemented with linked list

#### Tree

- Each node leads to multiple other nodes
- Binary tree leads to at most two other nodes

#### Other Linked Data Structures

Binary tree

#### Generics: Outline

The Basics

Programming Example: A Generic

**Linked List** 

### **Basics of Generics**

- Beginning with Java 5.0, class definitions may include parameters for types
  - Called generics
- Programmer now can specify any class type for the type parameter
- View class definition class Sample<T>
- Note use of <T> for the type parameter

#### **Basics of Generics**

- Legal to use parameter T almost anywhere you can use class type
  - Cannot use type parameter when allocating memory such as anArray = new T[20];
- Example declaration

```
Sample <String> sample1 =
  new Sample<String>();
```

Cannot specify a primitive type for the type parameter

# Programming Example

- Generic linked list
  - Revision of listing 12.5
  - Use type parameter E instead of String
- Note similarities and differences of parameterized class with non-parameterized classes
- View generic class

```
class LinkedList <E>
```

# Programming Example

### Summary

- Java Class Library includes ArrayList
  - Like an array that can grow in length
  - Includes methods to manipulate the list
- Linked list data structure contains nodes (objects)
- Linked data structure is self-contained by making the node class an inner class

## Summary

- Variable or object which allows stepping through linked list called an iterator
- Class can be declared with type parameter
- Object of a parameterized class replaces type parameter with an actual class type
- Classes ArrayList and LinkedList are parameterized classes
